²University of Huelva, Spain, climent@uhu.es

In this study we explore the potential relationships between the specialised knowledge of two university lecturers in linear algebra and their beliefs about mathematics teaching and learning. We scrutinise the lecturers' knowledge with the aid of the model Mathematics Teacher's Specialised Knowledge (MTSK), from which the subdomains Knowledge of topics (KoT), Knowledge of mathematics teaching (KMT) and Knowledge of features of learning mathematics (KFLM) enable us to establish associations with their beliefs. We found that the beliefs manifested by these two lecturers about methodology and subject significance are related to their KoT in terms of procedures and applications, KMT in terms of examples for teaching, and also to KFLM in terms of student errors.

Keywords: specialised knowledge, beliefs, university lecturer, linear algebra.

INTRODUCTION

Amongst studies into mathematics education, teachers' knowledge has received special attention. There has been found to be a connection between this knowledge and the teacher's beliefs, and both contribute to the quality of teaching. There have been few studies directed towards the relationship between university lecturers' knowledge and their beliefs about teaching and learning mathematics. We presented the findings of one study, focusing on the specialised knowledge deployed by a lecturer when teaching the topic of matrices and determinants, in a paper at the CERME meeting in the Czech Republic (Vasco, Climent, Escudero-Ávila, & Flores-Medrano, 2015). The paper presented here develops this line of research, examining possible relationships between the specialised knowledge displayed by two linear algebra lecturers, and their beliefs about teaching and learning mathematics.

MATHEMATIC TEACHERS' SPECIALISED KNOWLEDGE

In the last few decades, teachers' knowledge has attracted a great deal of interest from researchers, and various frameworks have been developed for the purpose. In our case, we have made use of the model *Mathematics Teachers' Specialised Knowledge* (MTSK) (Carrillo, Climent, Contreras, & Muñoz-Catalán, 2013). This model was developed in response to the difficulties experienced in applying the model *Mathematics Knowledge for Teaching* (MKT) (Ball, Thames, & Phelps, 2008), specifically with respect to the characterisation and demarcation of the different subdomains into which it is constituted, and aims instead to represent the specialised

nature of teachers' knowledge as an integral and inseparable element of that knowledge.

The MTSK model comprises two knowledge domains: *Mathematical Knowledge* (MK) and *Pedagogical Content Knowledge* (PCK). In addition to these two domains, and in a relation of mutual permeability with them, are teachers' beliefs about mathematics and how the subject is taught and learnt. These operate on teachers' classroom practice. MK is itself constituted by the subdomains *Knowledge of topics* (KoT), *Knowledge of the structure of mathematics* (KSM) and *Knowledge of practices in mathematics* (KPM). For its part, PCK includes the subdomains *Knowledge of mathematics teaching* (KMT), *Knowledge of features of learning mathematics* (KFLM) and *Knowledge of mathematics learning standards* (KMLS). For details of the subdomains and categories making up the framework, readers are directed to previous CERME presentations (Carrillo et al., 2013; Vasco et al., 2015) and related papers (Vasco, Climent, Escudero-Ávila, Montes, & Ribeiro, 2016). In this paper we limit ourselves to a brief overview of the subdomains KoT, KMT and KFLM, as it is these which allowed us to establish the relationships between the teachers' specialised knowledge and their beliefs about teaching and learning mathematics.

KoT is defined as a thorough, grounded knowledge of mathematical content. It comprises the categories of *phenomenology and applications* (knowledge of phenomena associated with the meanings of a mathematical topic and ways a topic can be applied), *properties and fundamentals* (knowledge of properties which fulfil a mathematical objective or are necessary to carry out a procedure), *representations* (knowledge of the different ways a topic can be represented), *definitions* (knowledge of descriptions and characterisations of a concept, including related examples, along the lines of the constructs *concept definition* and *concept image* developed by Tall & Vinner, 1981), and *procedures* (knowledge about how, under what conditions and why something is done, and the key features which result in doing it).

KMT, as the name suggests, concerns knowledge about the teaching of mathematics and includes the following categories: *theories of teaching* (that is, specific to mathematics education), *material and virtual resources* (books, whiteboards, software, and so on as tools for teaching mathematics), and *activities, tasks and examples for teaching* (knowledge of examples for teaching a mathematical idea and their potency for the topic in question). It is important to distinguish between teachers' knowledge of examples relating to definitions, which, as noted above, pertain to KoT, and those relating to examples for teaching, which are the provenance of KMT, and allow teachers to highlight features specific to particular topics. In this respect, Bills et al., (2006) note that the deployment of examples in class is complex, involving careful choice in directing learners' attention adequately so as to reach the right generalisations.

The authors classify the different types of examples into generic examples (examples of concepts and illustrations of procedures), counterexamples (in support of an opposing hypothesis or proposition relating to a concept, procedure or step in a demonstration), and non-examples (of use in demarking the boundaries of a concept or procedure, or in demonstrating the conditions of a theorem). In considering how to maximise the effectiveness of the use of examples in teaching mathematical concepts, Blanco, Figueiredo, Contreras, & Mellado (2011) focus on the attributes *transparency* and *variation*. Transparency refers to degree to which the key aspects of the example are evident to the learner, such that it becomes a point of reference. In the case of variation Watson & Mason (2005) consider *dimensions of possible variation*, along which certain aspects or details might change while remaining within the limits of being a recognizable example of the concept in question (different ways of approaching the same concept).

Finally, KFLM is knowledge about how mathematics is learned. The chief focus is not on the student, but rather on mathematical content as the object of learning. The categories included here are: *learning styles* (knowledge of theories of the cognitive development of the student), *areas of strengths and weaknesses associated with learning* (that is, of the student in regard to the content), *the students' forms of interacting with the content* (knowledge of student strategies), and *the student's motivation with regard to mathematics* (knowledge of students' expectations about the content).

BELIEFS ABOUT TEACHING AND LEARNING MATHEMATICS

Teachers' knowledge and beliefs interact (Charalambous, 2015), and these interactions can lead to a better understanding of both aspects. In this paper we present possible connections between the subdomains of the specialised knowledge of two linear algebra teachers and their beliefs about the mathematics teaching and learning.

We are aware that different positions can be taken in relation to the terms "beliefs" and "conceptions". As the individual's set of incontrovertible personal truths, beliefs are an important means of taking account of the affective aspects of the teacher's personality. Conceptions, on the other hand, can be considered as a conceptual substrate, influencing all aspects of a cognitive nature and playing a key role in determining the teacher's thinking and actions (Ponte, 1994). In this study we will use the term "beliefs" to refer indistinguishably to conceptions and beliefs (as discussed above), although aware that our focus is chiefly cognitive.

In order to study the lecturers' mathematics teaching and learning beliefs (MTLB), we drew on the classifications in Carrillo & Contreras (1994) for tendencies (*traditional, technological, spontaneous* and *investigative*) and categories (*methodology, subject significance, learning conception, student's role, teacher's role*). Each category has corresponding indicators by which teachers' beliefs can be inferred. The aim is to arrive at an interpretative description of the teacher's beliefs, rather than assign the

teacher to any specific tendency. For example, in the category *methodology*, the following indicators describe teachers' orientation in terms of classroom practice: 'repetition of [N type] exercises characterise classroom practice' (*traditional* tendency); 'the exercises aim to reproduce logical thought processes and, in consonance with this, error analysis by the students (*technological* tendency). In the case in hand, both descriptors help us to describe the conceptions of Carlos and Jordy regarding their classroom practice, with a view to identifying associations with their specialised knowledge, without delving into their corresponding teaching tendencies.

METHODOLOGY

This is a qualitative study, taking a case-study design (Yin, 2003). It focuses on two lecturers teaching linear algebra in the first year of a degree course at the University, and who, for the purposes of this study, will be referred to as Jordy and Carlos. We attempt to provide an answer to the research question, 'What interaction is there between the specialized knowledge of two linear algebra lecturers and their beliefs about mathematics teaching and learning?' In this paper, due to limitations of space, we will focus principally on the knowledge which is manifested in the use of examples. The two lecturers were chosen for their willingness to take part in the study and our intrinsic interest in the teaching cohort to which they belonged, with a view to subsequent participation. Jordy is a graduate of the Educational Sciences faculty, specializing in mathematics, with 22 years' experience in teaching mathematics at secondary level and 9 years at the university. Carlos is a geologist with 17 years' experience of teaching mathematics in the university.

Data collection was carried out via class observations (using video recordings) and semi-structured interviews. The topic of *matrices, determinants and systems of linear equation* was chosen to be observed as it was first in the study programme for the course in linear algebra, and essential for tackling subsequent topics. The analysis of these data followed the procedures of content analysis (Bardin, 1996), sifting through the teachers' actions and statements for evidence of knowledge pertaining to the appropriate MTSK subdomains, and beliefs about mathematics teaching and learning, using throughout the categories outlined above – from the MTSK model in the case of knowledge, and the analytical tools in Carrillo & Contreras (1994) in the case of beliefs.

RESULTS

Tables 1, 2 and 3 summarise the relationships between the teachers' knowledge and their beliefs. With regards to *methodology*, both lecturers pursued procedural objectives with their classes, demonstrating an interest in their students gaining mastery of the operations and algorithms associated with the mathematical content in question. Jordy and Carlos ascribed an instrumental end to teaching matrices (*subject significance*), of interest because they provide solutions to systems of linear equations or to find the value of a variable. This is made clear in their interviews:

Jordy: [In answer to what he wanted his students to learn about matrices] To be able to do the required operations, pose problems involving matrices and know how to solve them. Because matrices allow you to solve systems of equations.

Carlos: When we're talking about matrices, we're talking specifically about variables, and there are different procedures for finding variables when we apply matrices.

Evidence of knowledge about scenarios requiring the use of the content and potential applications (KoT – *phenomenology and applications*) is demonstrated in the case of Jordy through mathematical situations (solving systems of equations, fundamentally), and in the case of Carlos through some situations which could arise in real life. The kind of knowledge displayed in these instances would seem to be consistent with their beliefs about the *subject significance* of matrices (that is, serving practical ends, with high value given to the ability to reproduce the content further on in time). Below are the relevant excerpts from their interviews:

Jordy: Now we need to turn our attention to vectors, and after that other areas based on matrices, so you see that this content is important because of what comes later in terms of calculus and differential equations.

Carlos: I give the students practical examples from real life, so that they can see that matrices are not just applicable to a specific science, but to any area, such as nutrition, sport, or a factory.

There was also evidence of associations between the teachers' knowledge about KoT – *procedures* and their beliefs about teaching – *methodology*. Jordy chooses not to present the content as a unitary procedure; instead, he sets up a series of exercises which aim to reproduce the logical processes involved. Carlos, on the other hand, does decide to present the content in this way, and the lesson activity is marked by the repetition of exercises. In setting up the class in this way, Jordy manifests a depth of knowledge pertaining to the category KoT – *procedures*, which leads him to go beyond a plain exposition of the procedures in order to underline the reasons underlying their use. In the case of Carlos, the knowledge in evidence is of the type KoT – *procedures, How is something done*, and hence his knowledge would appear to be external to mathematics, attuned to an eminently utilitarian view of the subject.

Categories and indicators of beliefs	MTSK
<p><i>Methodology</i>: replicating patterns of thought (Jordy) and mechanical (Carlos).</p> <p><i>Subject significance</i>: Orientation (applicability), Objective (informative, utilitarian) (Jordy and Carlos)</p>	<p>KoT-<i>procedures</i>: <i>How is something done?</i> (Jordy and Carlos) and the reasoning underlying procedures (Jordy).</p> <p>KoT- <i>phenomenology and applications</i>: applications to mathematics itself (Jordy) and applications to real life (Carlos).</p>

Table 1: Associations between beliefs and KoT of Jordy and Carlos

There are also associations between Jordy's knowledge of examples for teaching (KoT – *examples for teaching*) and his beliefs about *methodology*. Jordy seems to conceive of the role of the lecturer as that of replicating the process of building knowledge via a selection of examples which allow different features of the content to be highlighted. The extract below is from his introduction to the topic of multiplying matrices:

Jordy: In order to add matrices we need to meet a condition. What was it?

Student: They need to have the same dimensions.

Jordy: They need to have the same dimensions. In order to multiply matrices we also need to meet a condition. If we take matrix A $\begin{bmatrix} 2 & 3 & 1 \\ 4 & -5 & 0 \end{bmatrix}$ What are the dimensions of this matrix?

Student: Two rows, three columns.

Jordy: The dimension is 2x3. To multiply two matrices we need the number of columns in the first matrix to be the same as the number of rows in the second matrix. If A looks like this, B has to have three rows, it doesn't matter how many columns it has. Let's imagine that matrix B is a column matrix $\begin{bmatrix} 1 \\ -3 \\ 5 \end{bmatrix}$ It can be multiplied with this one, the only condition is that it has three rows. The dimensions of this matrix are . . .

Student: 3x1

Jordy: If the matrix doesn't meet this condition, then as you say it cannot be multiplied [...] [The lecturer writes two matrices, 3x2 y 3x4.] What we do is we take the first row of matrix A and we multiply it by the items in the first column of matrix B [...].

Jordy generally presented the content using three of four examples, in this case avoiding entering into the topic of multiplying square matrices of the same order so as to make it clear to the students how important it is to define the dimensions of the matrices to be multiplied in order to determine whether it can be carried out or not. Jordy employed a wide variety of generic examples (Bills et al., 2006), which meant that he could focus students' attention on the more salient features and on aspects providing a wide range of images. We associate this knowledge of examples with *Knowledge of Mathematics Teaching* (KMT). The examples used by Jordy show evidence of transparency (Blanco et al., 2011), given that the matrices A(2x3) and B(3x1) used by the teacher are aimed at directing learners' attention towards salient aspects of the content (the dimensions of the matrices). In addition, the teacher draws attention to aspects that might vary in the examples employed (*dimensions of possible variation*, Watson & Mason, 2005), in this case the possible dimensions of matrix B in relation to A (leading to the examples B(3x2) and B(3x4)).

Furthermore, Jordy’s conceptions are aligned with a kind of classroom practice favouring what could be called replicative structured exercises (that is, the student exercises are designed to encourage them to replicate the logical thought processes). He warns students about potential pitfalls along the way. This conception, considered in *methodology*, is associated with his knowledge about errors and difficulties in learning (KFLM – *areas of strengths and weaknesses associated with learning*). Hence, when dealing with the topic of multiplying matrices he advises the students to define the dimensions in order to avoid falling into the common error of applying the algorithm for adding matrices, multiplying (in the case of matrices with the same dimensions) elements in corresponding positions (as he explains in an interview):

Jordy: The error that they can always fall into first is thinking that they have to multiply number by number according to the position it’s in. So, at least in this case, multiplying matrices, I tend to bang on about dimensions.

Thus, his knowledge of students’ learning difficulties with respect to the content (KFLM) is associated with his knowledge about examples for teaching content (KMT) and his conceptions about *methodology* (replicative structured exercises, with emphasis on warning students about pitfalls). At the same time, his knowledge of examples is related to his conception of *teacher’s role* (presenting content by means of replicating the process of its construction).

Categories and indicators of beliefs	MTSK
Methodology: replicating patterns of thought with emphasis on errors	KFLM- <i>weaknesses associated with learning</i> : transposition of algorithm for adding matrices to multiplication; failure to note dimensions of matrices
Teacher’s role: deliver content by replicating process of knowledge construction	
	KMT- <i>examples for teaching</i> : variability of examples

Table 2: Associations between Jordy’s beliefs and his KMT and KFLM

In Carlos’ case, his knowledge about the category of *examples for teaching* (KMT) is intertwined with his beliefs about *subject significance*, that is, that the point of the subject is essentially informative with practical applications in everyday life. To this end, the lecturer develops the work on matrices around a set of exercises intended to reproduce real life situations (with the matrices representing, in this case, models of cars for different routes and with different fuel efficiency).

Carlos: I always give you practical examples so that you get an idea of how they can be applied [...] You can see here that we’ve got two tables with information about different situations. The first gives different routes followed by four makes of car (3x4), while the second table shows the petrol consumption for each of the models over the five week days (4x5). If we put them into matrix form will they be the same or not?

Student: No, they won't.

Carlos: No, but that isn't what matters in this case. Here, the layout they're in is the right one to multiply them because what we do is multiply the rows by the columns; so the number of columns in the first matrix coincides with the number of rows in the other one [...] We have to multiply the element which is in the first row, first column of table T by the element which is in the first row, first column of table G [...].

By going through exercises of this kind, the need to define the operation (the multiplication of matrices) emerges, and this approach is consistent with the lecturer's beliefs regarding framing what needs to be learned in practical terms. In this case, in terms of the lecturer's beliefs, methodology would seem to be based on the repetition of such exercises, with less emphasis on the logical processes involved and on errors (unlike the case of Jordy). The lecturer's KoT is evident in procedures (*how it is done*, essentially) and phenomenology (*application of content to other fields*).

On the other hand, regarding his pedagogical content knowledge, Carlos displays KMT with regard to examples for teaching. His knowledge, which would seem to be primarily related to the practical purposes to which the contents can be put, does not directly correspond to any of the categories in Bills et al. (2006), so much as to phenomenological examples. The example is transparent (Blanco et al., 2011) in the sense that directs' students' attention and illustrates a procedure (the product of matrices).

Categories and indicators of beliefs	MTSK
Methodology: mechanical repetition of exercises	KMT- <i>examples for teaching</i> : examples of applications to real life
Subject significance: purpose (informative and practical)	

Table 3: Associations between Carlos' beliefs and his KMT

CONCLUSIONS AND IMPLICATIONS FOR FUTURE RESEARCH

Having established the relationships between them, we can see how the knowledge and beliefs of the two lecturers studied interact. Their conceptions enable us to better understand their knowledge and vice-versa. Their conceptions about *methodology* and *subject significance* are consistent with the KoT (regarding procedures and applications) which each of them manifests in their practice. Likewise, their conceptions about *methodology* (class practice activities with exercises which replicate patterns of thought versus activities focusing on mechanical repetition, with possible emphasis on errors), and *teacher's role* indicate an association with the KMT that each demonstrates (in terms of knowledge of examples for teaching); in the case of emphasising error avoidance, there is an association with their KFLM (in terms of

knowledge of errors). Both aspects (beliefs and knowledge) are reflected in the elements they give emphasis to in the course of their teaching. Hence, dealing with the multiplication of matrices, one of the lecturers chooses to emphasise the conditions required to apply the procedure and the avoidance of potential errors, the other the applications to real-life situations.

Teachers' knowledge and ways of thinking are essential to the teaching of mathematics, and need to be understood in order for teachers to be helped to improve their practice, and consequently their students' learning (Chapman, 2015). We have carried out an initial approach towards establishing relationships between teachers' knowledge and their conceptions about the teaching and learning of mathematics, and this contributes to our understanding of how and why teachers do what they do in the classroom. Detailed analysis of teachers' knowledge and conceptions about mathematics teaching and learning can help us gain a broader vision of the relationships between these two constructs. Furthermore, it would be interesting to explore further where the associations that have been uncovered lead, how they might influence, for example, the teacher's beliefs in generating specialized knowledge.
